

## The Full Model

## Location Table

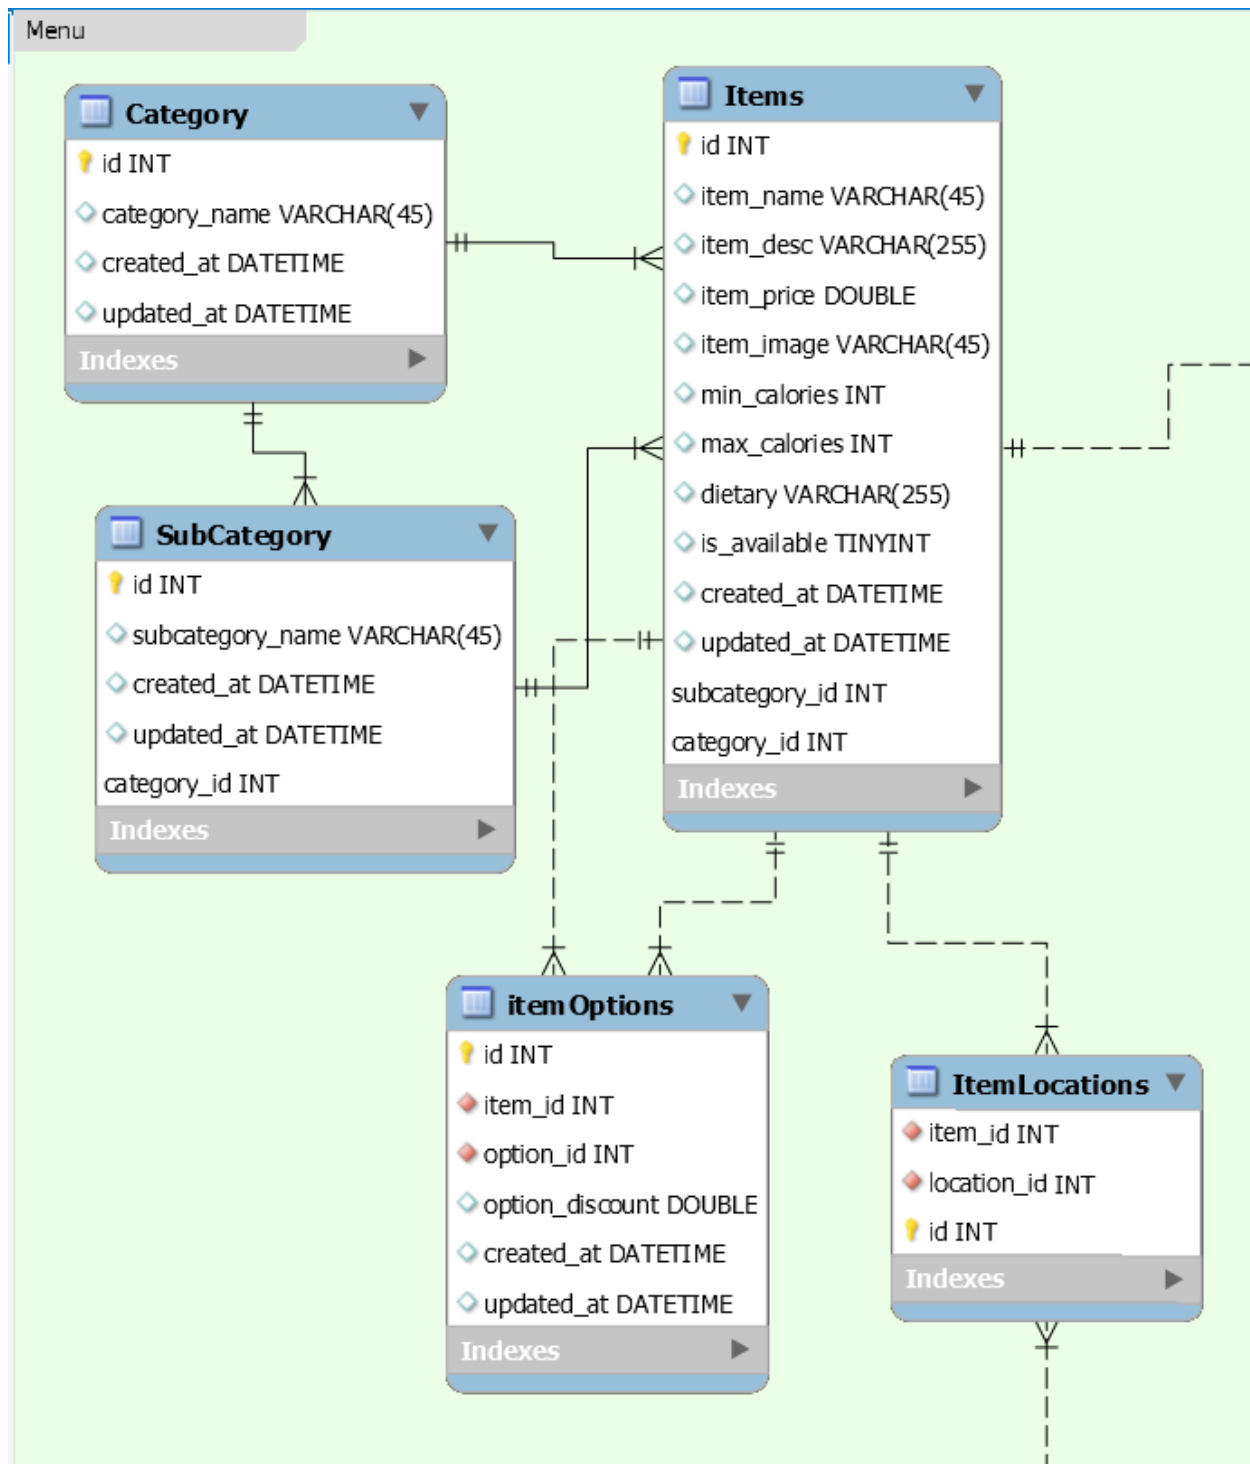

location_name	varchar	A nickname for a location	required
address1	varchar	First address line	required
address2	varchar	Second address line	required
city	varchar	City of address	required
state	varchar	state/province of address	required
post_code	varchar	Postal code of address	required
country	varchar	Country of address	required
county	varchar	County of address	required
is_restaurant	boolean	Whether or not the location is a restaurant location	required (filled out depending on which form the location was added from [admin vs web user])

## The User Section

The user section is where we store all users involved. One thing to notice is the relationship of User-to-Group and User-to-Permission is many-to-many. That means permissions do not need to be assigned on user registration, but can be assigned after the fact.

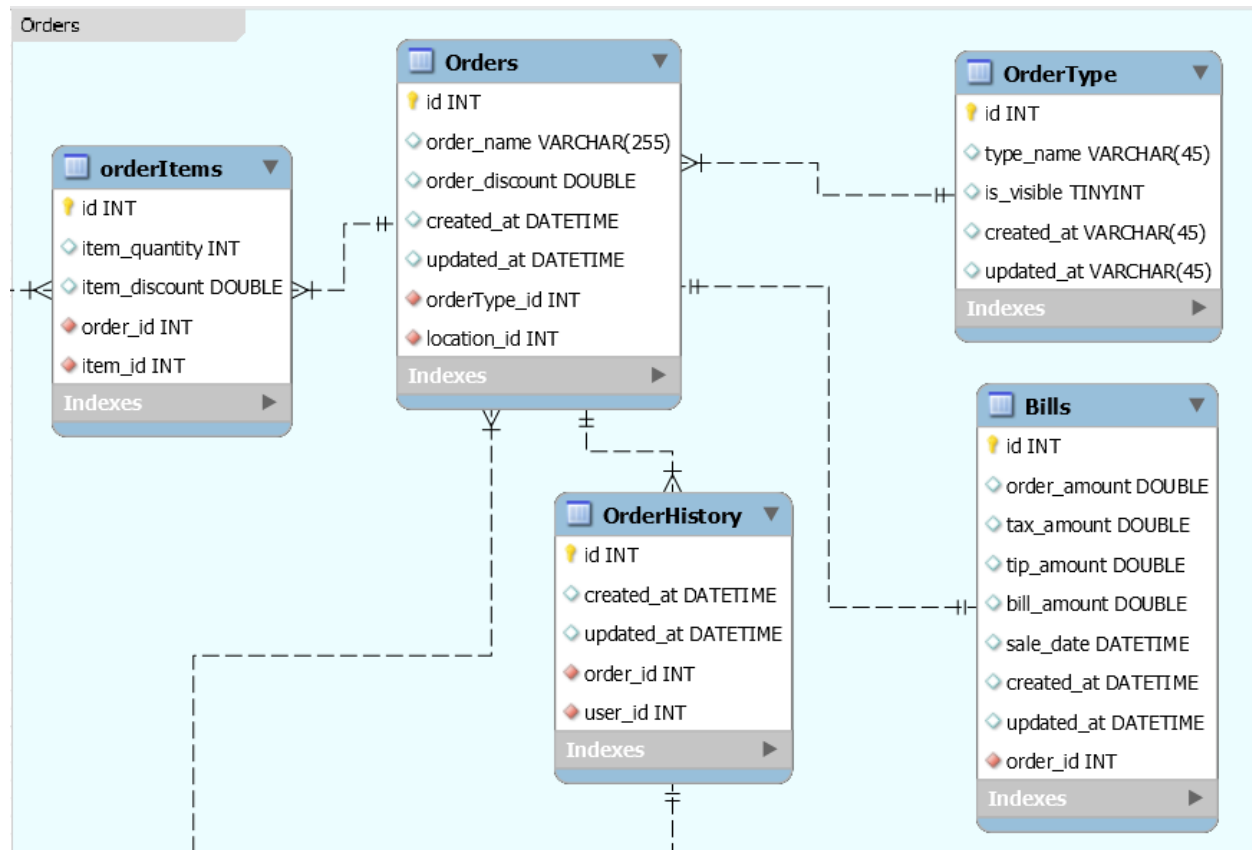

# The Menu Model

The Menu model is where the food items that can be ordered are located. The only strange relationship that is not straightforward is the Item-to-ItemOptions. The best way to think of this relationship is if there is an option on an item, it is another item of the category Option. I'm a

little unsure how to explain in text form atm, but we will probably have to talk through it together to make sure we all understand how it works.

# The Order Model

This is where we will deal with the POS orders and online orders along with storing the base information needed for tracking Bills.
